SUMMARY

DevOps Engineer who takes services from application code through Docker, Terraform, GitHub Actions, and production on AWS and on-premises Windows Server. Owns repeatable deploys, SHA-tagged images, Linux/Nginx operation, and alerts for host, API, and database health.

SKILLS

Infrastructure: Docker, Docker Compose, AWS (EC2, VPC, S3, ECR, IAM), Terraform, Linux, Nginx, Prometheus, Grafana, Loki, Alertmanager

Automation: Python, Git, GitHub Actions, cron / scheduled backups, production deploys

Application context: Django, FastAPI, Go, PostgreSQL

Additional: Redis, MongoDB, Kubernetes (familiar — not production)

EXPERIENCE

DevOps / Backend Engineer — Meraki Innovation

Jan 2025 – Present

Mirpur 2, Bangladesh

- Owned CI/CD and Terraform-based production deploys across on-prem Windows Server and AWS so releases are repeatable rather than one-off copies.
- Ran production Docker Compose on EC2 for a client Education SaaS: Nginx in front, health checks, and daily PostgreSQL dumps to S3.
- Operated the release path for a live multi-tenant dashboard so widget and RBAC changes shipped through those same deploys, not as one-off copies.

Backend Developer — Cooking Station

Sep 2024 – Dec 2024

London, United Kingdom

- Maintained a live Django MVT product: bug fixes, new features, and a customized admin panel used in day-to-day operations.
- Integrated third-party APIs and cron jobs so operational work did not sit inside a single request/response cycle; redesigned parts of the database schema under changing production requirements.

PROJECTS

Education Institutions SaaS — production deploy path | Go/Gin, PostgreSQL, Redis/Asynq, Docker Compose, Terraform, GitHub Actions, AWS · [Case study](#)

- Provisioned VPC, subnets, security groups, and EC2 with Terraform. Compose on EC2 is the deploy unit (Nginx, API, workers, Postgres).
- GitHub Actions runs format, vet, lint, tests, and image vulnerability scanning, then publishes SHA-tagged images to ECR. A manual deploy workflow rolls the compose stack. Secrets via GitHub Actions and EC2 env files; IAM roles split for CI/CD vs infrastructure.
- Ran daily PostgreSQL dumps to S3 with a documented rebuild: new EC2, restore the dump, redeploy Compose, reattach S3. Single-EC2 is a known SPOF. Observability beyond health checks is not shipped; application source is private.

ServeEasy — live restaurant product | Django, Docker, PostgreSQL, Nginx, Prometheus · [Live](#)

- Operated a dedicated EC2 Compose stack (Nginx, Django API, Postgres, MCP). Application source is private.
- Stopped a recurring PostgreSQL “too many clients” failure by tuning how the API holds database connections.
- Cleared EC2 root-disk pressure from ~90% to ~55% using df, docker system df, and container stats, without replacing the instance.
- Added a second EC2 in the same VPC for Prometheus, Grafana, Loki, and Alertmanager; Alloy ships that host's container logs to Loki.
- App host exports Node Exporter, cAdvisor, API, and Postgres metrics; only the observability security group can scrape them. Alerts: CPU above 85%, memory or disk below 15%, restart loops, API 5xx above 5%, Postgres above 32 of 40.
